Overview

What is the purpose of this API; just a short text.

Concepts

(Only if API has new concepts that need to be understood in order to use it)

Architecture

(Only if API is sufficiently complex and interacts with other parts of the system)

Implementation

No details, just a few generic points how it works internally.

Usage

This is how the API can be instantiated in the system.

Declaration of API library in CMake

Some short text about how to declare the API in the **CMakeLists.txt**:

The API library can be compiled in three different modes:

- `os_api_x`
- `os_api_y`
- `os_api_z`

Example

Describe example for the usage for all the relevant parts.

Instantiation of API in CMake

See above, just with concrete names and parameters.

Component Example 1

```
DeclareCAMEKESComponent(  
  <NameOfComponent>  
  SOURCES  
  
  C_FLAGS      ...  
  
  LIBS         ...  
              ...  
              os_api_x  
)
```

Using the API in C

Maybe add some minimal code examples..

Keep it minimal: We have the doxygen documentation to document all the parameters, functions, etc.

Component Example 2

```
#include "API.h"  
  
static const API_cfg = {  
}  
  
...  
  
int run()  
{  
    API_init(&hApi, &cfg);  
  
    API_do(x, y);  
  
    API_free(hApi);  
}
```
